

Ensuring the future of perennial crops in Southeast Asia in a context of global change : case of Garcinia fruit tree species.

OBJECTIFS

MANNGIS will focus on a key perennial crop, the mangosteen (*Garcinia mangostana*; Clusiaceae), as one of the most desirable tropical fruits of the region.

Mangosteen's place of origin and cultivation history remain unknown, but it is believed to have originated from a wild relative species in the Malay archipelago. *Garcinia malaccensis* and *G. hombroniana* are often cited as candidates, although this needs to be verified.

ACTIONS

WP 2. Effects of calcareous soil and high temperature on genome expression

RESULTATS

MANNGIS will allow:

unravelling the respective status of these species, as well as the cultivation history of mangosteen
identifying zones of high or particular genetic diversity to be conserved

contributing to the establishment of CSM&U strategies

PERSPECTIVES

A number of wild *Garcinia* species are still neglected (and threatened by deforestation), yet they can contribute to diversity in markets and to diets. These species need to be characterized (diversity, distribution, threats, nutrition, agronomic and economic potential, etc), and MANNGIS will provide a methodological framework to be replicated
